## Moore's Law Scaling Realities for Storage Components: LTO TAPE, HDD and NAND

- Moore's law for integrated circuits
- Moore's law scaling applied to storage: bit areal density and cost per bit
- Bit areal density and \$/gigabits trends for TAPE, HDD, and NAND (3 and 8 yr periods)
- Cost scaling deviations and other problems
- Summary

## What is Moore's law?

- 1965: Gordon Moore observed that the number of transistors, resistors and capacitors in an integrated circuit (IC) had been increasing exponentially ( $2 x$ per year); this implied that the unit cost of the transistors, etc., that could be crammed into an IC was decreasing exponentially
- 1975: Moore refined his observation and made projection that IC complexity would double every

2 years (with IC cost remaining static) - this became known as 'Moore's Law'

- The implication of this is the unit cost of the transistors, etc., will decrease $2 x$ every 2 years
- There is a close parallel to this for digital data storage

## Bits, areal density and scaling

- In storage architectures, dimensions of the bits (the 1's and 0's) determine bit areal density
- Thus, bits are analogous to transistors, resistors, etc., and the aggregate area of the all the bits, to an IC
- For NAND, bit dimensions are photo lithographically defined (more akin to the paradigm behind Moore's law)
- Scaling means improvements in photo lithography ( $X$ and $Y$ ) and other IC processes ( $X, Y$ and $Z$ )
- For magnetic storage, the bit dimensions are established during writing the bits onto the magnetic medium
- Bit width $(X)$ is set by the width of the write head (HDD) or shingling pitch (TAPE, some HDD)
- Bit length $(Y)$ is set by the writing frequency and speed of the magnetic medium under the head
- Scaling means narrower written tracks and shorter bit length

## Moore's exponential law for storage: bit areal density, cost per bit

- In storage technology, bit areal density (D) ideally increases exponentially with an annual growth factor of (1+ $\alpha$ )
- Year 0: $D=D_{0}$
- Year $N: \quad D_{N}=D_{0} \times(1+\alpha)^{N}$
- If the cost / unit area of storage is constant, then the cost per bit (C) decreases exponentially with an annual decrease factor of (1- $\beta$ )
- Year 0: $C=C_{0}$
- Year $N: \quad C_{N}=C_{0} \times(1-6)^{N}$
- And the relationship between the 2 factors is:
- $\beta=\alpha /(1+\alpha)$
- Thus, an 'ideal' Moore's law IC scaling equivalent for storage components would give:
- Bit areal density doubling every 2 years, i.e $\alpha=0.41$ ( $41 \%$ annual increase)
- Cost / unit of media area remaining constant $\rightarrow$ cost / bit halves every 2 years, i.e $b=0.29$ (29\% annual decrease)

But...current storage areal density gains are less than Moore's 41\%*

| AREAL DENSITY <br> $\left(\right.$ Gbit $\left./ \mathrm{in}^{2}\right)$ | 2008 | 2015 | 2016 | 8 YEAR <br> ANNUAL <br> $\% \Delta$ | 3 YEAR <br> ANNUAL <br> $\% \Delta$ | 1 YEAR <br> ANNUAL <br> $\% \Delta$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| LTO TAPE <br> MEDIA $^{1}$ | 0.9 | 4.1 | 4.1 | $21 \%$ | $25 \%$ | $0 \%$ |
| HDD | 380 | 1000 | 1100 | $14 \%$ | $7 \%$ | $10 \%$ |
| NAND | 200 | 1500 | 2000 | $33 \%$ | $33 \%$ | $33 \%$ |

1. LTO products on 2 year product cycle, 2017 LTO8 product will increase 1 year and 8 year averages

- NAND increases are closer to Moore's at $33 \%$ and show no decrease in this rate
- LTO TAPE MEDIA doubles on ~ 3 year cycle, or 25\% annually, and shows no slowing in this rate
- HDD increases are << Moore's scaling; 8 year increases reduced to $14 \%$ and show significant slowing in recent time frames
- Blu-ray AD is stable, at most increasing slowly
*In the period 2003-2011, HHD density did grow at 39\% / year

And...currently, reductions in cost per bit are less than Moore's 29\%

| \$/GB | 2008 | 2015 | 2016 | 8 YEAR <br> ANNUAL <br> $\% \Delta$ | 3 YEAR <br> ANNUAL <br> $\% \Delta$ | 1 YEAR <br> ANNUAL <br> $\% \Delta$ |
| :--- | :--- | :--- | :--- | :---: | :---: | :---: |
| LTO TAPE <br> MEDIA $^{1}$ | 0.091 | 0.018 | 0.016 | $-19 \%$ | $-10 \%$ | $-10 \%$ |
| HDD | 0.272 | 0.051 | 0.039 | $-21 \%$ | $-18 \%$ | $-23 \%$ |
| NAND | 3.330 | 0.401 | 0.320 | $-25 \%$ | $-20 \%$ | $-20 \%$ |

1. Data source change from 2014 to 2015 distorts LTO averages

- $29 \%$ decreases in cost per bit are not being achieved
- NAND $\$ /$ GB shows a 3 year average drop of $20 \%$
- HDD \$/GB shows a 3 year average drop of $18 \%$
- LTO TAPE MEDIA \$/GB (distorted by a change in LTO data sources) shows a $10 \%$ drop
- Blu-ray cost per bit is stable, no drop

## An important distinction between HDD and TAPE

- Disk cost is unit cost of the HDD brick, which includes platters, heads, electronics, etc.
- Tape cost is for the media cartridge only; drive cost is typically included in automation and is significantly less than the cost of the media

## \$/GB and areal density 'dynamics'

cost / unit area of storage
media is constant

This plot is a generalization of Moore's-like exponential scaling for storage. Recall that Gordon Moore's prediction for IC's was a doubling every 2 years (the 'dot') at constant IC cost

## \$/GB and areal density 'dynamics'

- LTO TAPE, NAND: 8 yr data follow a Moore's law trend, while 3 yr data fall below it, implying (1) market forces and/or (2) greater investment was needed for the gain in density
- HDD: 8 yr and 3 yr data are above the Moore's law trend, implying (1) market force competition and/or (2) the modest areal density gains did not drive up cost
- Observation 1: Historical 8 yr data shows \$/bit for all technologies fell between $20 \%$ to $25 \%$ annually
- Observation 2: Historical 3 yr data shows lower \$/bit reductions for all technologies relative to 8 yr data

## What are the scaling REALITIES

- Present day storage component trends are not meeting Moore’s law for ICs
- Annual density increase is not $41 \%$, but ranges from $10 \%$ to $30 \%$ (depending on technology)
- Cost per bit decrease is not $29 \%$, but closer to $10 \%$ to $20 \%$, (depending on technology)
- Critically, the cost to produce a unit area of storage is NOT remaining constant, but rather is increasing
- Physics and the required linewidths associated with scaling bit cells are raising development costs
- Marketing forces
- Further, the landscape of storage component manufacturers is changing
- Fewer competitors (both HDD and TAPE)
- Manufacturing capacity constraints (NAND)
- Limited market (Optical)

## And...cost effective bit-scaling is becoming more difficult

- Feynman famously stated in 1959 (the year the first integrated circuits were built), 'there is plenty of room at the bottom,' i.e. you can always make things smaller
- 1959 minimum features $\sim 1500$ um
- 2017 minimum features ~ 0.015 um
- In 60 years linewidths fell by $\sim 10^{5}$ and cell areas fell by $\sim 10^{10}$
- 2017 NAND chips ( $12 \mathrm{~mm} \times 12 \mathrm{~mm}$ ) contain $256 \times 10^{9}$ bits, while chips in 1960 contained 1 to 5 bits [1]
- Thus, for ~ 50 years, the Moore's law 'contract' had been: reduce component cost per bit by finding 'room at the bottom' with smaller bit cell devices at the same cost per unit total storage area
- In the last 5 years, the 'art' of making bit cells smaller, though, has increased the cost of a unit area of storage

## Bit cell dimensions

- TAPE: room at the bottom, so continue scaling (Moore's law)
- HDD: no room at the bottom so add more platters (not Moore's law)
- OPTICAL: some room at the bottom, limited by $\lambda$, so add more layers (not Moore's law)
- NAND: no room at the bottom, so add more layers at the media level, but process layers simultaneously (close to Moore's law)

40 layers, or more

7TB 12" wafer
44012 mm x 12 mm dies / ~ 256 Gb/die

10TB 3.5" drive
7-8 platters / ~ 1.4TB/platter
1.2TB cartridge

12 platters / ~0.1 TB/platter

3 layer
land recording 180 nm diameter $75 \mathrm{Gbit} / \mathrm{in}^{2}$

[^0][^1]
## NAND

NAND 3D TLC
40 layers
$3 \mathrm{bit} / \mathrm{cell}$
$84 \mathrm{~nm} \times 84 \mathrm{~nm}$
$3000 \mathrm{Gbit} / \mathrm{in}^{2}$

7TB 12" wafer<br>$44012 \mathrm{~mm} \times 12 \mathrm{~mm}$ dies<br>~ $256 \mathrm{~Gb} / \mathrm{die}$

- Areal Density Strategy is adding more layers
- Cost / bit reductions are maintained provided all layers are processed in a single step to form individual stacked bit cells
- Continued scaling and Moore's law are limited by ability to continually double number of layers
- Density increase of 4 X to $\sim 128$ layers and 4 bits per cell are in the offing
- Cost per bit decrease of 4 X less likely since 'tiered' processing of layers is required, i.e. process the first 64 layers and then the second 64 layers, etc.

| $\frac{\mathrm{HDD}}{58 \mathrm{~nm} \times 11 \mathrm{~nm}}$ |  |
| :--- | :--- |
| $1000 \mathrm{Gbit} / \mathrm{in}^{2}$ | 10TB 3.5" Drive |
|  | $7-8$ platters $/ \sim 1.4 \mathrm{~TB} /$ platter |

- Volumetric strategy is adding more disk platters, with minimal increase in aerial density
- Cost / bit in transitioning from 4 TB to 10 TB capacity was managed by moving from 4 to 7 or 8 platters, but this meant increasing the manufacturing area for components (heads and disk surfaces)
- Scaling and hence Moore's law gains are limited by ability to continually double number of platters
- Density increase of 2 X possible but addition of more platters will be difficult
- Cost / bit reductions have limited scaling potential due to difficulty of increasing areal density, e.g. HAMR

HAMR is needed to enable significant HDD bit length scaling

ASTC Technology Roadmap

shrinking HDD bit dimensions faces challenges in both directions: $X(S M R)$ and $Y$ (KBPI)

6TB cartridge, 1000 m tape length
LTO TAPE
$3200 \mathrm{~nm} \times 47 \mathrm{~nm}$
4 Gbit/in ${ }^{2}$
15TB cartridge, 1100 m tape length
Enterprise TAPE
$1350 \mathrm{~nm} \times 47 \mathrm{~nm}$
$9 \mathrm{Gbit} / \mathrm{in}^{2}$

- Areal Density Strategy is classical planar scaling, i.e. making the bit cell smaller
- Cost likely is likely to be managed since (1) classical scaling is used, (2) TAPE uses HDD existing technology ('no new physics'), and (3) length scales and media particle sizes will scale for the future
- Cost dynamics may be influenced by market sources
- 4X density increases providing > 40 TB cartridge capacities are only 4 years on the horizon
- The Future TAPE Demonstration (2017)

103 nm x 31 nm
207 Gbit/in ${ }^{2}$

Tape has room to continue bit scaling in both $X$ and $Y$ directions

TAPE scaling requires 'no new physics'

## SUMMARY

- Moore's law for ICs (doubling density every 2 years, and cost / bit halving every two years) is not being achieved by LTO TAPE, HDD, NAND (NAND being the closest)
- Bit cell scaling is loosing cost efficiency
- Physics, e.g. HAMR
- Processing smaller features - nano technology limits (HDD, NAND)
- Cost-per-bit reductions are trending to less than 20\% / year
- Market forces are now impacting \$/GB reductions
- 3 year and 8 year trends show decrease in \$/GB reductions for all technologies
- There is an under-capacity in NAND (not enough factories to meet HDD demand in foreseeable future)
- HDD market has shifted from personal devices to datacenter applications
- There is tape consolidation (1 drive manufacturer, 2 media suppliers)

## Optical BD-XL

Optical BD-XL
3 layer
land recording
180 nm diameter
$75 \mathrm{Gbit} / \mathrm{in}^{2}$

1.2TB Cartridge<br>12 disks<br>~ 0.1TB/platter

- Areal Density Strategy is adding more storage layers on the plastic disk substrate
- Cost per bit likely not well managed, since the patterning or processing of each storage layer is done individually
- A 2-sided $3+3$ layer disk may have $2 X$ the capacity of the single sided 3 layer disk but at close to $2 x$ the cost of the single sided 3 layer disk.
- Scaling, and hence Moore's law geometric figure of merit gains, are limited by ability to simultaneously process individual layers
- Land and groove recording will likely increase density by 1.5 X at the expense of error rate
- Cost per bit reductions have limited potential with land and groove recording, providing the potential for only a one time $30 \%$ reduction in cost per bit
