Questions

- ◆ What software technology are you most concerned about for preservation archives in terms of reliability of the bits, and why?
 - ◆ All technologies related to obsolescence of formats and software
 - ◆ Only a “solved” problem for static data types
 - ◆ No support for dynamic data, e.g., Web sites
 - ◆ Automation
 - ◆ Collecting metadata
 - ◆ Verifying metadata
 - ◆ Determining format obsolescence
 - ◆ . . .
- ◆ What software technology are you least concerned about for preservation archives in terms of reliability of the bits, and why.
 - ◆ Migration of the bits to address media obsolescence
 - ◆ Multiple technologies exist and have been used for years
 - ◆ Although room for improvement

Preservation DataStores: Storage Assist for Preservation Environments

- ◇ OAIS-based
- ◇ Independent of the underlying physical storage layer (tape, disk,...)
- ◇ Generic, independent of the type of stored data
- ◇ Scalable (e.g. global namespace)
- ◇ Offloading functionality to the storage layer
 - ◇ Decrease the probability of data loss
 - ◇ Simplify the applications
 - ◇ Provide improved performance and robustness
 - ◇ Utilize locality properties
 - ◇ Compute data intensive functions internally e.g. fixity
 - ◇ Provide better support for links among objects
- ◇ Part of EU CASPAR Project
 - ◇ Cultural, Artistic and Scientific knowledge for Preservation, Access and Retrieval
 - ◇ <http://www.casparpreserves.eu/>

Preservation DataStores: A New Storage Paradigm

Functionality	Rational
Physically co-locate the Information Object (AIP)	Ensure metadata is never lost when raw data survives
Execute data intensive functions at the storage component: <ul style="list-style-type: none">◆ fixity computations and validation◆ data transformation	Utilize the data locality property
Handle provenance events internally	E.g. migration and copy occurs at the storage
Support the loading and execution of external transformations	Ideally performed during bit-migration performed close to data

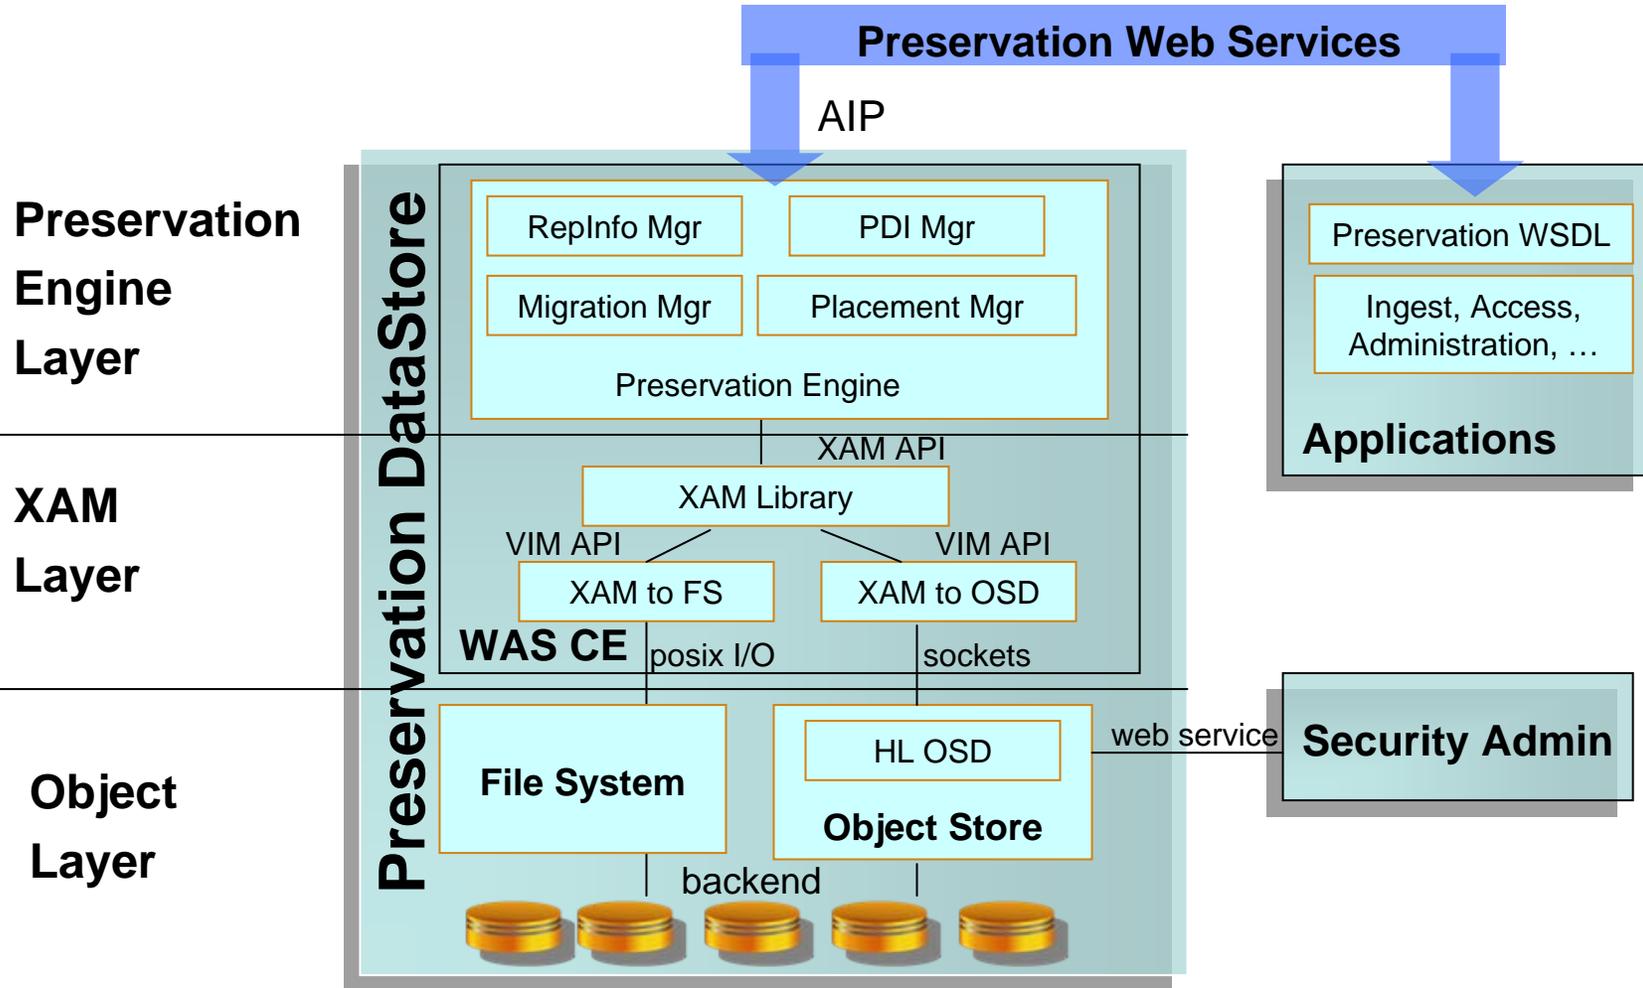

Preservation DataStores: A New Storage Paradigm (Cont.)

Functionality	Rational
Maintain referential integrity Update links during migration	Ideally done during migration
Ensure readability of the data by a different system in the future. Support global self-described formats	Interaction with backend storage
Support media migration Load and execute transformations Portable export format	Interaction with backend storage
Support a graceful loss of data Self-describing self-contained media format	Minimize the effect of media loss/corruption

Preservation DataStores: Architecture

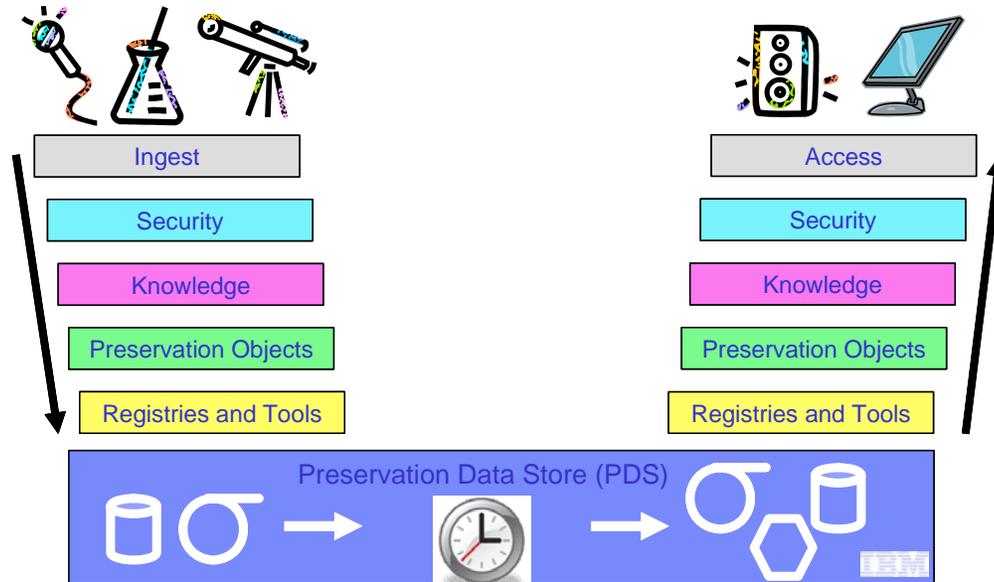

Backup

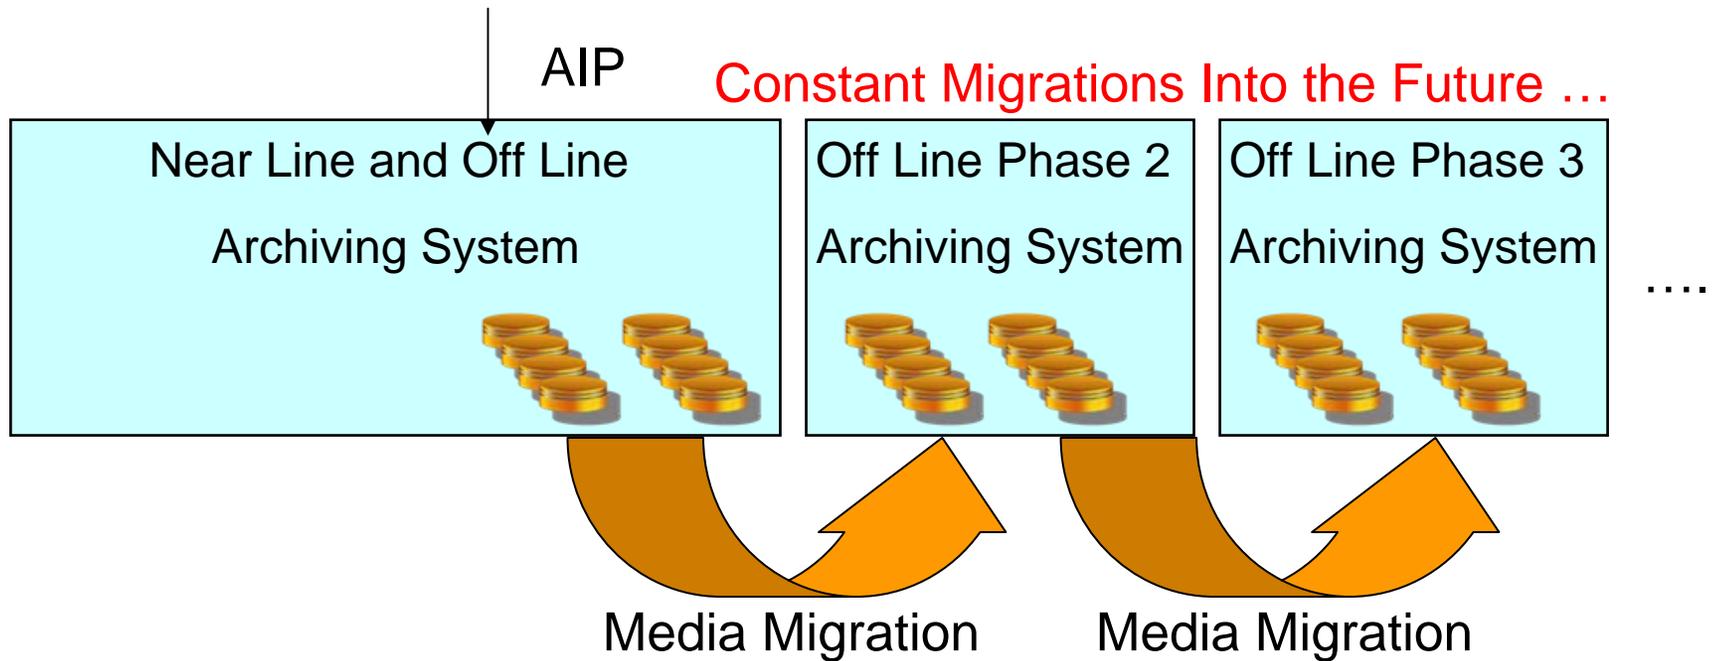

CASPAR and Preservation Data Stores

- ◆ CASPAR: Cultural, Artistic and Scientific knowledge for Preservation, Access and Retrieval
 - ◆ 8.8M Euro, 3.5 year, EU Project
- ◆ Demonstrate validity of OAIS framework with heterogeneous data

Migration with Self-Describing Self-Contained Media Format

- ◆ Encapsulation of data and metadata is done within the tape/disk subsystem
- ◆ Migration is simple – just move the tape to the new system
- ◆ If a tape is damaged or lost, the effect is contained – the information in the other tapes is still valid!
